Abstract: [Authors' English summary modified] Studies on inmates of a home for aged disclosed that discurbances of equilibrium frequently appear in aged people and increase with age. As a rule, the excitability of the labyrinth is impaired and graduelly decreases. The symptoms are connected with changes in the central nervous system. Of the four references, one (1) is Polish, one (1) Gorman, and two (2) French.

TITLE: Investigations on pyrolytic decomposition of propane-butane mixtures

PERIODICAL: Przemysł Chemiczny, v. 39, no. 3, 1960, 170 - 175

TEXT: This article is a continuation of research described in Prz. Ch. v, 37, 175. Its subject was pyrolytic decomposition of synthetic "gazol", i.e., the mixture of liquefied propane and butane. In subject article, pyrolytic decomposition of natural "gazol" (natural liquefied gas) is described. The pyrolysis was carried out in heat resisting steel, stainless steel "KNR" (18/8), copper and quartz pipes. As a result of the study into the influence of temperature in the range of 650 - 800°C and contact time 0.6 - 127.5 sec. on the courde of the pyrolysis of propane-butane mixtures to ethylene-propylene, several regularities were observed. Optimum contact times have been found at various temperatures and in reactors made from materials mentioned above. Confirmation is given of the previously deduced empirical rule, which established that the logarithm of optimum contact time, in the range of temperatures examined, is a linear function of temperature. In the reactors described, using natural and synthetic liquefied

petroleum gas, the weight ratios of ethylene and propylene at the given temperature and optimum contact times (ethylene-propylene pyrolysis) have been found to vary within fairly close limits. The composition of the "natural gazol" is: H₂ + CH₁ = 0.3 - 0.1%; CO₂ = 0.1%; C₂H₁ = trace; C₂H₆ = 0.3%; C₃H₈ = 48.9 - 46.1%; C₁H₁₀ = 56.2 - 53.4%. Constructional materials have little effect on results. There are 9 figures, 4 tables and 6 references; 2 Soviet-bloc and 4 non-Soviet-bloc. TITLE:

Dehydration of Isopropylbenzene to Alpha-Methylstyrene Over a

Styrene Catalyst

PERIODICAL: Przemysł Chemiczny, 1960, Vol. 39, No. 9, pp. 576 - 580

TEXT: The author presents the results of his investigation on the dehydration of isopropylbenzene to α-methylstyrene in a tubular reactor (Fig. 1) over the zinc-type styrene catalyst. The aim of this investigation, conducted during 1955 - 1957, was to determine the optimum parameters of the dehydration process. The influence of temperature, catalyst feed and dilution of isopropylbenzene with steam upon the output of α-methylstyrene was investigated. Data obtained are represented graphically in 3 graphs and compiled in 3 tables. Based on these data, the following optimum parameters of the process are given: temperature -580°C; volumetric velocity of isopropylbenzene - 0.20 to 0.40 l/h and the weight ratio isopropylbenzene/steam - 1 : 1.0 to 1 : 30 g/g. Under these conditions the conversion of isopropylbenzene was 44.9 - 46.5%; the content of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene in the oil of the tubular reactor - 39.0 to 40.0%; the yield of α-methylstyrene yield y

TITLE: Mechanism of thermal decomposition of paraffin hydrocarbons

PERIODICAL: Wiadomości chemiczne, no. 1, 1961, 39-50

. .

TEXT: The present paper is a compilation, own studies are not mentioned. In the introduction, the author gives the following summary of his paper: "The mechanism of thermal decomposition of paraffin hydrocarbons is discussed in the light of some authors opinions. The research work for explaining the participation of free radical and molecular chain processes in the thermal decomposition of hydrocarbons is described." After a chronological survey of the data obtained by western authors, the author passes over to his own paper, Ref. 60: Rozk/ad termiczny alkanów i odwodornienie izopropylbenzenu w procesie otrzymywania alfa-metylstyrenu z krajowych gazoli, Praca doktorska, Gliwice 1959 (Thermal cleavage of alkanes and dehydrogenation of isopropyl benzene in the synthesis of a-methyl styrene from domestic gas oils, dissertation). He studies the initiation of the separation of a propane-butane mixture by means of tetraethyl lead and silicon-hydrogen

Card 1/3

P/016/61/000/001/002/002 B115/B208

Mechanism of thermal ...

peroxide, as well as the inhibition by propylene. The studies were carried out by the dynamic method in a quartz reaction vessel under atmospheric pressure and at temperatures of 550-650°C (initiation) and 700°C (inhibition). The factors applied were found to have neither a sensitizing nor an inhibitory effect under these conditions. On the basis of the results it is assumed that there are essential differences in the mechanism of thermal separation of the same compound under different conditions of the process. The hypothesis according to which the role of the chain mechanism is of fundamental significance seems to hold for low pressures and temperatures; at elevated pressures and temperatures corresponding to the parameters of industrial pyrolysis, this hypothesis is without any foundation. It is assumed that, under the latter conditions, either the chain processes are insignificant, or the chains are very short. Non-chain processes might play an important part in this connection, such as molecular processes. It may be seen from the survey of publications that the mechanism of thermal separation of hydrocarbons is not yet clarified. The participation of freeradical chain processes in the pyrolysis seems to be proved, but the extent of this participation under different separation conditions and the cole of molecular processes in carbon pyrolysis are not yet clear. The assumption Card 2/3

CONTROL CONTRO

Mechanism of thermal ...

P/016/61/000/001/002/002 B115/B206

of Hinshelwood (Ref. 61) that free-radical chain processes and molecular reactions coexist in the separation processes of paraffins (and not only of paraffins), both determining the course of the process, seems likely. The following Soviet-bloc publications are mentioned: A. I. Dintses, A. V. Frost (Ref. 20: ZhoKh, 1933, 2, 747); Z. K. Mayzus, V. G. Markovich, M. B. Neyman (Ref. 32: ZhFKh, 1949, 23, 1187); M. N. Emanuel' (Ref. 33: Promezhutochnyye produkty slozhnykh gazovykh reaktsiy (Intermediates of complicated gas reactions) Izd. AN SSSR, Moscow-Leningrad 1946); A. D. Stepukhovich (Ref. 53: DAN SSSR, 1953, 90, 213; Ref. 54: ZhFKh, 1958, 32, 2571). There are 2 tables and 61 references: 8 Soviet-bloc and 53 non-Soviet-bloc. The four most recent references to English-language publications read as follows: F. O. Rice, K. F. Herzfeld (Ref. 13: J. Am. Chem. Soc., 1934, 56, 284); C. N. TIME

On some dependencies in the process of alkano-alkene mixture pyro-

lysis

PERIODICALs Przemysł Chemicany, v. 40, no. 1, 1961, 37-39

TEXTs The purpose of the research described in this article was to electedate the influence of alkanes mixed with oleftnes on the process of pyrolysis. In order to do it, in a series of experiments, pyrolysis of propane-tutane mixture containing various quantities of ethylene, propylene and butylenes was carried out. As the propane-rutane mixture the liquefied natural gas, called "gazol", containing 50.2% of butane and 48.9% of propane (by vol.) was used. From "gasol" and 98.8% pure alkenes (ethylene, propylene and butylenes) desired mixtures were prepared and processed by the olefinic pyrolysis in a tubular laboratory reactor. The pyrolysis was carried out at 750°C, 1.5 1/min sas flow rate and about 3 seconds of contact time. The proportion of alkenes in mixed gas varied from 0 to 40% by volume. The meaning of symbols used in the calculation is: k - the coefficient of gas volume increase during the pyrolysis process,

Card 1/4

On some dependencies in the process ...

entropy continues and the second of the seco

P,114/61/040/001/006/007 A221/A126

 $k_{\rm alk}$ - the coefficient of gas volume increase in relation to the volume of alkenes in the original gas mixture, x - the yield of all alkenes in relation to the total gas processed, W - the yield of alkenes obtained from processed alkanes, assuming the non-changeability of alkenes in the original mixture. The coefficient of volume increase was calculated as follows:

$$k = \frac{V''}{V''} \qquad (1); \qquad k_{alk} = \frac{V'' - V_0}{V' - V_0} \qquad (2)$$

where V' = the volume of gas in liters before pyrolysis, V'' = the volume of gas after the pyrolysis and V_0 = the volume of the diluent (alkenes) in liters in the mixed gas before the pyrolysis. When analysing the results, several interesting regularities were observed: 1) As the proportion of alkenes in the initial gas mixture increases, the volume-increase coefficient k decreases. It was found that at a certain defined range, it is an approximate linear function of alkene content and what more, it is independent from the kind of alkene present in the gas. 2) The increase of gas-volume coefficient $k_{\rm alk}$, proved to have a constant value within the limits from 0 to approximately 20% by vol. of alkenes in gas mixture, again regardless of the kind and quantity of same. It had the same value as the coefficient k for pure "gazol" at identical decomposition

Card 2/4

On some dependencies in the process ...

F,0.4/6./040/001/006/007 A221/A126

conditions. These conclusions allow to estimate the state of dependency between the volume-increase coefficient k and the content of alkenes (or alkanes) to the alkene-alkano gas mixture. From the equations (1) and (2) and by introduction of the expression $a_{\chi}=\frac{V_0}{V_{\chi}}$, by simple algebraic operation, the author arrived at an equation $k=\frac{k+a_{\chi}}{1-a_{\chi}}$ where k_0 (4), where k_0 is the volume-increase

coefficient of pure alkanes in identical decomposition conditions. Hence $k=(1-k_0)\,a_X+k_0$ (5), or, taking into consideration that $a_X+a_{alk}=1$, $k=(k_0-1)\,a_{alk}+1$ (6), where a_{alk} is the voluminal part of alkanes in the initial gas mixture. On the basis of the experiments described above the author arrived at following conclusions as to the behaviour of alkanes in the initial gas mixture during the process of pyrolysis: The stability of the k_{alk} coefficient and the linear variability of the posificient k, when small quantities of alkanes are present, can be explained by a secondary decomposition of same at which the volume contraction takes place. In other words, alkanes decompose partly to gaseous products causing volume increase, and partly to liquid or solid products, causing equivalent volume contraction. With larger quantities of alkanes in gas mixture, (over 20% of ethylene and propylene and 10% of outylenes) Card 3/4

On some dependencies in the process ...

F,014/61/040/001/005/007 A221/A126

the rate of secondary decomposition increases. The process leading to volume contraction (formation of carbon and tar) takes place before the process leading to volume increase, i. e. formation of gaseous products. Consequently, the value of W drops considerably along with the coefficient $k_{\rm alk}$, which was fairly steady when less alkenes were present in the mixture. No particular influence by any specific alkene on the pyrolysis was noted. There are 3 figures, 3 tables and 3 references: 2 Soviet-bloc and 1 non-Soviet-cloc. The reference to the English-language publication reads as follows: H. Pines, T. am. chem. Soc., 55, 3892 (1933).

TANIEWSKI 5816 7 547.538.141:547.313 Maronski T., Tamiewski M. The Pyrolysis of Alkanes from Synthetic Gas Oil as a Supplementary Source of Oicfins for u-Methylstyrene and Siyrene Manufacture. "Piroliza alkanów z gazolu syntetycznego jako dodatkowe źródło olefin dia produkcji alfa-metylostyrenu i styrenu". Przemysł Chemiczny. No. 7, 1958, pp. 475-482, 9 figs., 8 tabs. This paper deals with the most economical utilization, under Polish conditions, of gas oil from the Fischer-Tropsch synthesis for obtaining isopropylbenzene and ethylbenzene as intermediates for manufacturing a-methylatyrene and styrene. In addition to olefins, uso was made of the alkane components of the gas. A description is given of the results of laboratory examination of the ethylene-propylene pyrolysis of sikane components in pipe reactors of copper, KNR-steel, and steel resistant to temperatures 600-750°C. for a period of contact from 1.4 to 113 sec. The optimum time of contact at various temperawere and in different pipes was established together with the best yield of ethylene and propylene obtained under such conditions. A description is also included of the methods of preliminary treatment

XX.

of the pipes to suppress the undesirable catalytic influence on the course of the process (poisoning with H_iS, mercaptans). Study of the influence of water vapour on the trend of pyrolysis at 750°C. in a temperature-registant pipe (at \tau about 2.5 sec.) showed that the optimum content of water in the mixture was 15% by weight, the yield of ethylene, propylene and carbon being respectively: 37.8%,

ABSTRACT:

An electronic pickup, consisting of a transmitter and a receiver, has been developed in the Soviet Union for signaling the moment a tank crosses the cease-fire line on the training range. This instrument is presently being introduced into the tank forces. The electronic pickups operate in the millimeter radio-wave band, and are reliable under any weather conditions (at temperatures from -40 to +50C), and with power fluctuations of from -20 to +15% of the normal current. TITLE:

Checking Drawbar Dynamometers

PERIODICAL:

Izmeritel'naya tekhnika, 1959, Nr 9, p 31 (USSR)

ABSTRACT:

The author describes a device for checking drawbar dynamometers which was developed by the balance repair shop at the Leningradskiy metallicheskiy zavod (Leningrad Metals Plant). According to results of state tests, this device was approved for checking drawbar dynamometers. The error of this device is ± 0.2%, while the permissible error for drawbar dynamometers is ± 2%. Previously, the checking of drawbar dynamometers was rather time-consuming and three to four people had to move a total of 18 tons of weights. The time for checking was reduced by 10-12 times and only one man is required. The device consists of the lever mechanism of a crane balance, a frame to which this mechanism is mounted, and a cable winch with a reductor. The device is 1,500 mm high, 1,200 mm long and 250 mm wide. Its total

Card 1/2

Checking Drawbar Dynamometers

SOV/115-59-9-17/37

weight is 250 kg. One end of the drawbar dynamometer is connected to the cable, while the other end is connected to the lever mechanism of the crane balance. The crane balance permits the setting of any weight. For checking the set weight of the crane balance is compared with that of the drawbar dynamometer according to a procedure describes by the author. There is 1 diagram.

Title : On Central Mechanisms of Shock

Orig Pub : Tr. Konferentsii po electrotravme, 1956, Frundze, AN

KirgSSR, 1957, 39-48

Abstract : The manifestations of parabiosis and dominance lie at

the basis of shock conditions which are subject to the law of optimum relative physiological lability. On the basis of a critical survey of literature, the conclusion is made that the published experimental data and clinical observations testify to the greatest fruitfulness and methodological substantiation of the views of those domes-

tic researchers on the mechanism of shock who depart from the positions of N.E. Vvedenskiy and his school. --

The Pyrolysis of Light Distillate Oil (Piroliz gazovogo benzina) · TITLE:

Study of Pyrolysis Under Semi-industrial Conditions (Izucheniye

piroliza v poluzavodskikh usloviyakh)

PERIODICAL:

Khimicheskaya promyshlennost', 1958, Nr 6, pp 333-335 (USSR)

ABSTRACT:

An analysis of the pyrolysis of liquefied gas (Tuymazinsk) for the production of a raw material for unsaturated compounds was carried out on a semi-technical scale. The gasoline consists mainly of a pentane-hexane fraction. A schematic drawing and description of the testing plant are given. The analysis of the gas obtained by pyrolysis was carried out in the apparatus Told -51 and THE. The results obtained are given in a table and indicate, among other th_ngs, that a temperature increase does not only result in a higher yield of gas, but also in an increased concentration of ethylene. Optimum conditions stated are as follows: temperature of 220°, a contact time of one second, and an addition of steam to the extent of 20 per cent by weight. Under these

Card 1/2

The Pyrolysis of Light Distillate Oil Study of Pyrolysis Under Semi-Industrial Conditions

SOV/64-58-6-3/15

conditions the yield of gas obtained by pyrolysis is 82 per cent by weight (of the raw material), the ethylene content being 31,8 per cent by volume, the content of propylene and ethane 7 and 4 per cent by volume, respectively. The yield of liquid carbon is 16 per cent by weight, 45,6 per cent of which boil at 78-112. If the gas obtained has a composition that is similar to that of the gases obtained by the pyrolysis of the ethane and propane-propyl fractions, it can be conducted to the separating unit along with the other gases, and it is not necessary to change the production units for the individual elefins. There are 4 figures and 3 tables.

TITLE:

Production of high-purity ethylene

PERIODICAL: Khimicheskaya promyshlennost', no. 2, 1962, 1 - 3

TEXT: Special purification methods of pyrogas for the production of high-purity ethylene are described. The study was conducted in an experimental plant with a productivity of 800 Nm3/h as follows: (1) Purification of the gas from sulfur compounds and carbon dioxide by means of 11.6% NaOH. The pyrogas is previously cooled to 15 - 18°C to eliminate polymerizable hydrocarbons, and purification is performed at a watering density of $7 \text{ m}^3/\text{m}^2$ ·h, a linear pyrogas velocity of 0.04 m/s, and a temperature of $\sim 50^{\circ}\text{C}$. (2) Dehydration of the gas in two stages: from an initial pyrogas moisture of 225 mg/Nm3 to 20 mg/Nm3, as well as from 20 to 10 mg/Nm³. Silica gel of the following specification was tested: volume weight 0.85 g/cm³; specific pore volume 0.320 cm³/g; specific surface 537 m²/g; average pore radius 11.8 Å. Dehydration of air and Card 1/3

ethylene was performed under laboratory conditions by means of molecular sieve of the NaA type produced at the GrozNII, the Gor'kovskaya opytnaya baza VNIINP (Cor'kiy Experimental Base VNIINP), and the Institut fizicheskoy khimii AN USSR (Institute of Physical Chemistry AS UkrSSR). The yolume weight of the molecular sieve varies between 0.45 and 0.7 g/cm3. (3) The purification of the ethylene-ethane fraction from acetylene may be realized by selective hydrogenation in the presence of catalysts, or (for more than 0.5% C_2H_2) by absorption with organic solvents. An industrial nickel-chrome catalyst was tested in an experimental plant. The ethylene-ethane fraction with a content of 0.025 to 0.19% acetylene was hydrogenated by the methane-hydrogen fraction of the pyrogas at 150 - 190°C, 23 - 25 atm, 4000 - 6000 h⁻¹ volume velocity, and a hydrogen concentration of 25 - 30% in the methane-hydrogen fraction. (4) Methane removal of the ethylene-ethane fraction by fractional distillation at -23 to - 32°C. The methane and carbon monoxide content in ethylene after methane removal was determined by the XT-2M (KhT-2M) chromatograph. Activated carbon of the type AP-3 (AR-3) was used as . adsorbent. There are 4 figures, 2 tables, and 7 references: 1 Soviet and
